

Data Structures in Python

Chapter 5

- Binary Search
- **Recursive Binary Search**

Agenda & Readings

- Binary Search
- **Recursive Binary Search**

Recursive Binary Search

- Binary search is an efficient algorithm for finding an item from **a sorted list** of items.
 - It works by repeatedly **dividing in half the portion of the list** that could contain the item, until you've **narrowed down the possible locations to just one**.

key=23

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
|---|---|---|---|----|----|----|----|----|----|
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

Recursive Binary Search

- For instance, we want to search "23" from the array. If we find it, we return its array index; otherwise, -1 or something else.

key=23

| | | | | | | | | | |
|---|---|---|---|----|----|----|----|----|----|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

(lo+hi)//2=mi

(0+9)//2=4

key>mi
23>16

| | | | | | | | | | |
|------|---|---|---|------|----|----|----|----|------|
| lo=0 | 1 | 2 | 3 | mi=4 | 5 | 6 | 7 | 8 | hi=9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

(5+9)//2=7

key<mi
23<56

| | | | | | | | | | |
|---|---|---|---|----|------|----|------|----|------|
| 0 | 1 | 2 | 3 | 4 | lo=5 | 6 | mi=7 | 8 | hi=9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

(5+6)//2=5

key=mi
23=23

| | | | | | | | | | |
|---|---|---|---|----|--------------|------|----|----|----|
| 0 | 1 | 2 | 3 | 4 | mi=5 lo=5 | hi=6 | 7 | 8 | 9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

Recursive Binary Search

- For instance, we want to search "23" from the array. If we find it, we return its array index; otherwise, -1 or something else.

| | | | | | | | | | |
|---|---|---|---|----|----|----|----|----|----|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

| | | | | | | | | | |
|------|---|---|---|------|----|----|----|----|------|
| lo=0 | 1 | 2 | 3 | mi=4 | 5 | 6 | 7 | 8 | hi=9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

| | | | | | | | | | |
|---|---|---|---|----|------|----|------|----|------|
| 0 | 1 | 2 | 3 | 4 | lo=5 | 6 | mi=7 | 8 | hi=9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

| | | | | | | | | | |
|---|---|---|---|----|--------------|------|----|----|----|
| 0 | 1 | 2 | 3 | 4 | mi=5 lo=5 | hi=6 | 7 | 8 | 9 |
| 2 | 5 | 8 | 9 | 16 | 23 | 31 | 56 | 62 | 71 |

| | |
|------|-------------------------|
| key | key sought |
| list | sorted array |
| mi | midpoint |
| lo | smallest possible index |
| hi | largest possible index |

```
def binary_search(list, key, lo, hi):
    if lo > hi: return -1

    mi = (lo + hi) // 2
    if key == list[mi]: return mi
    if key < list[mi]:
        return binary_search(list, key, lo, mi-1)
    else:
        return binary_search(list, key, mi+1, hi )
```

same for low new for high

new for low same for high

Recursive Binary Search

- Given the numbers 1 to 100, what is **the number of guesses** at most needed to find a specific number if you are given the hint 'higher' or 'lower' for each guess you make?
 - Since the numbers are sequential (or sorted), we can use binary search.
 - Look at the middle element: if it's after than the number we're looking for, search the first half. If it's before the number we're looking for, look at the second half.
 - Each check cuts the size of the list numbers in half; how many times can we do this?
 - If we think backwards, in terms of doubling the list, we'll need n doublings to generate a list of length $2^n = 100$. What is the value of n ?
 - Since $2^6 = 64$ and $2^7 = 128$ (or $\log_2 64 = 6$, $\log_2 128 = 7$), $n = 6.x$
Therefore $n = 7$ guesses will be enough.
- Binary search guarantees to take no more than $\log n$ guesses or comparison.
- More precisely, $\lceil \log_2 n \rceil$ if n is not a power of 2.

Exercise: Exception Filter

- The **exception filter** reads in a sorted array of strings from a file(which we refer to as the `whitelist`) and an arbitrary sequence of strings from standard input and write those in the sequence that are **not** in the `whitelist`.
- **For example:**
 - When checking the spelling of a word, you need to know only whether your word is in the dictionary (or `whitelist`) and are not interested in the definition.
- **Another examples:**
 - Your email application might use an **exception filter** to reject any messages that are not on a `whitelist` that contains the email addresses of your friends.
 - Your operating system might have an **exception filter** that disallows network connections to your computer from any device having an IP address that is not on a preapproved `whitelist`.
 - In a computer search, we keep the whitelist sorted in order of the key.
 - The array length n need not be a power of 2.

Exercise: Exception Filter

- **Task:** Find and print all misspelled words in `words.txt` using binary search algorithm. The correct words in `dict.txt` are listed in sorted order. A skeleton code, `dict.txt` and `words.txt` files are provided.
 - When checking the spelling of a word, you need to know only whether your word is in the dictionary (or **whitelist**) and are not interested in the definition.
 - We keep the **whitelist** sorted in order of the key.
 - The array length **n** need not be a power of 2.

whitelist in
sorted order

```
$ more dict.txt
accommodate
broccoli
conscience
definitely
embarrass
necessary
occurred
publicly
receive
separate
until
```

word list to check
misspelled

```
$ more words.txt
definatly
occured
occurred
untill
until
recieve
acommodate
seperate
separate
```

redirect standard
input through the file

```
$ python exfilter.py < words.txt
definatly
occured
untill
recieve
acommodate
seperate
```

misspelled words,
not in dict.txt (or
whitelist)

Exercise: Exception Filter

- Skeleton Code:

```
%%writefile exfilter.py
import sys

def binary_search(arr, key, lo, hi):
    pass

def search(arr, key):
    pass

if __name__ == "__main__":
    with open('dict.txt') as f:
        arr = f.read().splitlines()
    for line in sys.stdin:
        key = line.rstrip()
        if search(arr, key) < 0:
            print(key)                # not found in dict
```

```
%%cmd
python exfilter.py < words.txt
```

i/o reference: <https://stackoverflow.com/questions/1450393/how-do-you-read-from-stdin>

Exercise: Exception Filter

- Sample Runs in Jupyter Lab and in Windows cmd shell:

```
Overwriting exfilter.py

[2]: %%cmd
python exfilter.py < words.txt

Microsoft Windows [Version 10.0.19042.1288]
(c) Microsoft Corporation. All rights reserved.

C:\GitHub\DSpyx\jupyter>python exfilter.py < words.txt
definitely
occured
untill
recieve
acommodate
seperate

C:\GitHub\DSpyx\jupyter>

[3]: %%bash
python exfilter.py < words.txt

definitely
occured
untill
recieve
acommodate
seperate
```

Note: This does not work in Windows PowerShell. Use cmd.

```
C:\GitHub\DSpyx\jupyter>cmd
Microsoft Windows [Version 10.0.19042.1288]
(c) Microsoft Corporation. All rights reserved.

C:\GitHub\DSpyx\jupyter>python exfilter.py < words.txt
definitely
occured
untill
recieve
acommodate
seperate

C:\GitHub\DSpyx\jupyter>
```

Summary

- Binary search is simple, but powerful!
- Binary search may be implemented using either iteration or recursion.
- Its time complexity is $O(\log n)$.
